

Development Methodology

ATsys Adaptive Resilience Engine (ARE) has been developed through a human-centered engineering process supported by artificial intelligence.

The project's vision, objectives, engineering direction, and final design decisions are defined by its founder and engineering leadership.

Artificial intelligence has been used as an engineering design assistant to support system architecture, documentation, software design, technical analysis, brainstorming, and iterative development.

This methodology reflects the belief that the future of engineering lies in the collaboration between human expertise and advanced computational reasoning, while maintaining human responsibility for engineering judgment and project governance.
